Space Weather Technical Forecast

Issued on Wednesday 20 November 2024 at 12:03 Local

This technical forecast provides a four-day assessment of space weather events. The probabilities stated below are for reaching or exceeding the given levels. For more information about space weather impacts please see the Met Office Space Weather Scales https://www.metoffice.gov.uk/weather/learn-about/space-weather/uk-scales

---

Space Weather Forecast Headline: High Speed Stream solar winds bring a likelihood of enhanced geomagnetic activity from Day 2 (21 Nov).

Analysis of Space Weather Activity over past 24 hours

Solar Activity: Solar activity has been Low during the past 24 hours. The largest flare was a C9.0 at 19/1728 UTC from AR3901 in the southeast.

There are currently eight sunspot regions on the visible disc, one of which is currently unnumbered in the northwest quadrant. AR3889 has now rotated around the western limb, but given its magnetic complexity this still does pose a risk of both flares and protons from just beyond the limb. AR3901 in the southeast has some mixed magnetic complexity. AR3897 near the southwest limb also shows some complexity, although this region is becoming difficult to analyse as it approaches the western horizon. AR3898 has stalled in its growth and appears to be more stable. The other regions are relatively small and magnetically simple.

No Earth-directed CMEs were observed over the past 24 hours in available imagery.

Solar Wind / Geomagnetic Activity: Solar winds at L1 were mostly in a slow-regime between 340-400km/s, with a few brief peaks 420-430km/s. The solar wind density was near to below average. The interplanetary magnetic field (IMF), Bt, was weak to moderate, peaking around 12nT. The north-south component, Bz, showed periods of weak positive and weak to moderate negative orientation, peaking at -10nT. The phi angle was positive (away from the Sun) until around 20/1030 UTC when a period of negative (toward the Sun) was observed. The resultant geomagnetic activity was Quiet to Unsettled (Kp 1-3).

Energetic Particles / Solar Radiation: High energy proton flux observed by GOES18 remained at Background levels.

High energy electron flux (greater than 2MeV) observed by GOES16 was at Background to Moderate levels, with a diurnal peak of 745pfu observed at 19/1355 UTC. The associated 24-hour fluence remained below the Active threshold, and the 24-hour integrated flux observed at 20/0000 UTC was 1.31e7.

Met Office Space Weather Technical Forecast

Four-Day Space Weather Forecast Summary

Solar Activity: Low to Moderate activity is expected, with any east limb arriving regions contributing to a daily chance of M-class flares and a persistent slight chance of isolated X-class flares.

Solar Wind / Geomagnetic Activity: No Earth-directed CMEs currently feature in the forecast.

Slow-Ambient winds around 350-400km/s are expected during Day 1 (20 Nov) with an increasing risk of enhancement from CH93-/CH94- which are crossing into the western hemisphere. As a result, winds are expected to increase to Slightly elevated with speeds 450-500km/s arriving towards the end of Day 2 (21 Nov) and into Day 3 (22 Nov), gradually waning on Day 4 (23 Nov).

Quiet to Unsettled (Kp 1-3) conditions expected through much of the period. Activity probably increasing through Days 2 and 3 (21-22 Nov) becoming generally Unsettled to Active (Kp 3-4) for a time, with a chance of G1 Minor Geomagnetic Storm intervals, depending on the strength of any CH influences. Gradually easing to become mostly Quiet to Unsettled on Day 4 (23 Nov), as HSS influence wane.

Energetic Particles / Solar Radiation: There is a slight chance of S1/Minor solar radiation storms mainly due to ex-AR3889 which has now crossed over the western limb, but also the close proximity to AR3897 which follows closely behind. High energy electron flux is likely to remain at background to moderate (during diurnal peaks) throughout the period. The associated fluence is expected to remaining below the Active (1e8 integrated flux) threshold.

Geomagnetic Storms

There are currently no Earth-directed CME's in the forecast, although this can change at short notice. Especially if we see any significant filaments lifting from the Sun.

The main driver for any Geomagnetic activity through the coming period will be a connection to High Speed Streams originating from CH93-, shortly followed by CH94-. Slow-Ambient winds around 350-400km/s are expected during Day 1 (20 Nov) with an increasing risk of enhancement from CH93-/CH94- which are crossing the central meridian into the western hemisphere. Winds are expected to increase to Slightly elevated as a result, with speeds reaching 450-500km/s arriving towards the end of Day 2 (21 Nov) and into Day 3 (22 Nov). An enhancement in solar winds to 550-600km/s is currently suggested by MOSWOC Enlil output during Day 1 (20 Nov), although this is viewed with caution, probably considered too high and too early to bring in any enhancement.

Quiet to Unsettled (Kp 1-3) conditions expected through much of the period. Activity probably increasing through Days 2 and 3 (21-22 Nov) becoming Unsettled to Active (Kp 3-4) for a time, with a chance of G1 Minor Geomagnetic Storm intervals depending on the strength of any enhancement from CH93- and CH94- and any associated CIR region. Activity gradually waning on Day 4 (23 Nov), becoming mostly Quiet to Unsettled, with isolated Active intervals, especially at first.

Geomagnetic Storm Probability (Exceedance)	Level	Past 24 Hours (Yes/No)	Day 1 (00-24 UTC) (%)	Day 2 (00-24 UTC) (%)	Day 3 (00-24 UTC) (%)	Day 4 (00-24 UTC) (%)
Minor or Moderate	G1 to G2	No	1	20	20	10
Strong	G3	No	1	1	1	1
Severe	G4	No	1	1	1	1
Extreme	G5	No	1	1	1	1

Radio Blackouts - X-Ray Flares

There are currently eight sunspot regions on the visible disc, one of which is currently unnumbered in the northwest quadrant. AR3889 has now rotated around the western limb, but given its magnetic complexity this still does pose a risk of both flares and protons from just beyond the limb. AR3901 in the southeast has some mixed magnetic complexity. AR3897 near the southwest limb also shows some complexity, although this region is becoming difficult to analyse as it approaches the western horizon. AR3898 has stalled in its growth and appears to be more stable. The other regions are relatively small and magnetically simple.

Solar activity has been Low during the past 24 hours. The largest flare was a C9.0 at 19/1728 UTC from AR3901 in the southeast. Low to Moderate activity is expected, with a chance of isolated Moderate flares and a slight chance of X-flares.

X-Ray Flares Probability	Level	Past 24 Hours (Yes/No)	Day 1 (00-24 UTC) (%)	Day 2 (00-24 UTC) (%)	Day 3 (00-24 UTC) (%)	Day 4 (00-24 UTC) (%)
Active	R1-R2 (M Class)	Yes	50	50	50	50
Very Active	R3-R5 (X Class)	No	5	5	5	5

Solar Radiation Storms (High Energy Protons)

There is a slight chance of S1/Minor Solar Radiation storms over the period, chiefly due to any potential significant flaring from ex-AR3889, now just around the western solar horizon, but also AR3897 which is following closely behind. The series of inbound eastern limb regions are unlikely to present any appreciable risk to the daily probabilities of S1 in the near term.

Radiation Storms Probability (Exceedance)	Level ($cm^{-2}sr^{-1}s^{-1}$)	Past 24 Hours (Yes/No)	Day 1 (00-24 UTC) (%)	Day 2 (00-24 UTC) (%)	Day 3 (00-24 UTC) (%)	Day 4 (00-24 UTC) (%)
Active	**≥ S1**	No	5	5	5	5
Very Active	**≥ S3 ***	No	1	1	1	1
* S3 ≥ 10 MeV ≥ 1000 pfu and/or 50 MeV ≥ 10pfu. (pfu = $cm^{-2}sr^{-1}s^{-1}$)

High Energy Electrons (≥ 2MeV)

Electron flux levels at GEO have been sitting in a fairly constant diurnal cycle, dropping to background levels during the overnight period (in UTC) and peaking at Moderate levels during the UTC afternoon. This pattern is expected to continue, although electrons perhaps becoming suppressed as the Van Allen belt compresses due to increased solar winds from the connection into CH93-/CH94- during the second half of the period. Following this, electrons may increase again as the Van Allen belt expands back to the location of GEO.

The initial values unlikely to be of sufficient magnitude to trouble the Active 24-hour integrated threshold - no persistent feature on the disc has resulted in Active fluence. MOSWOC REFM output viewed as providing reasonable guidance at present.

GEO Electron Environment	Level ($cm^{-2}sr^{-1}$ day^{-1})	Past 24 Hours (Yes/No)	Day 1 (00-24 UTC)	Day 2 (00-24 UTC)	Day 3 (00-24 UTC)	Day 4 (00-24 UTC)
Probability (Exceedance)			(%)	(%)	(%)	(%)
Active	≥ 2 MeV ≥ 1×10^{8}	No	1	1	5	10
Very Active	≥ 2 MeV ≥ 1×10^{9}	No	1	1	1	1
